**HAL** is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

# 1 Introduction

If markets are complete then consumers have common shadow prices (namely the vector of market prices). So shareholders agree that firms should maximize profits with respect to these common prices. However, if markets are incomplete, shadow prices need not be common. Thus, typically shareholders disagree on the production plans to be chosen. Therefore several suggestions have been put forward as reasonable objectives for firms.

It seems natural that production plans should satisfy the Pareto criterion: there are no alternative production plans that make some shareholders better off and none worse off. Unfortunately, the Pareto criterion is weak: production plans satisfy the Pareto criterion if and only if they maximize profits with respect to some price vector in the convex hull of the shareholders' shadow prices.

Drèze (1974) and Grossman & Hart (1979) agree that production plans should satisfy the Pareto criterion and propose that sidepayments between shareholders be allowed. Drèze (1974) (resp. Grossman & Hart (1979)) suggests that production plans should reflect preferences of final (resp. initial) shareholders: this may be interpreted as production plans are determined after markets close (resp. before markets open). However, sidepayments depend on information that shareholders have incentives to manipulate, a weakness that voting rules overcome.

Drèze (1985) suggests that production plans should be stable for simple majority voting between shareholders and unanimity between board members (without sidepayments): there is no alternative production plan that makes all board members as well as a majority of shareholders better off. As in Drèze (1974) production plans reflect preferences of final shareholders. It appears to be a drawback that unanimity between board members is essential for existence of equilibria.

DeMarzo (1993) investigates some properties of equilibria where production plans are stable for simple majority voting between shareholders. Typi-

cally the largest shareholder determines the production plan at these equilibria. Also, DeMarzo shows that stability for simple majority voting between shareholders and unanimity between board members imply that board members determine the production plan. However, as he argues, such equilibria need not exist unless either the degree of market incompleteness or the dimension of the set of efficient production plans is 1.

In the present paper, stability with respect to  $\frac{1}{2}$  majority voting between shareholders is studied: there is no alternative production plan that makes more than  $\frac{1}{2}$  100 percent of the shareholders better off. Indeed, at a  $\frac{1}{2}$  majority stable equilibrium (or  $\frac{1}{2}$ MSE), consumers do not want to change their portfolios, firms are not able to make more than  $\frac{1}{2}$  100 percent of their shareholders better off by changing production plans and finally, markets clear. It is shown that if portfolios are unbounded then a  $\frac{1}{2}$ MSE exists provided that

$$\frac{1}{2}, \quad \min \frac{\frac{1}{2} S_{i,J}}{S_{i,J} + 1}; \frac{B}{B + 1} \geq \frac{3}{4}$$

where  $S$  is the number of states at the last date,  $J$  is the number of firms and  $B$  is the dimension of the set of efficient production plans for firms. If portfolios are bounded to be non-negative then a  $\frac{1}{2}$ MSE exists provided that  $\frac{1}{2}, B \geq (B + 1)$ .

Different timings of trade and vote are considered. Voting may take place while markets are open or after markets close, in which case final shareholders vote (as in Drèze (1985) and DeMarzo (1993)). And it may take place before markets open, in which case initial shareholders vote. In case of voting before markets open or while they are open, shareholders need to form expectations about price variations. Two types of price perceptions are considered: competitive price perceptions (as introduced by Grossman & Hart (1979)) and fixed price perceptions. According to competitive price perceptions consumers perceive that income vectors are valued by their shadow prices; whereas according to fixed price perceptions they perceive that prices are not influenced by changes in production plans.

In general, changes of production plans influence trading opportunities through two channels: they change the value of portfolios as well as the span of assets. From this perspective, competitive price perceptions and fixed price perceptions represent two extremes: consumers concentrate on how changes of production plans change the value of their portfolios with the former and the span of assets with the latter.

In case markets are complete, a  $\frac{1}{2}$ MSE exists even for unanimity, i.e. with  $\frac{1}{2} = 0$ . Ekern & Wilson (1974) have shown that this result extends to the case of partial spanning, i.e. the sets of efficient production plans are subsets of the span of assets<sup>1</sup>. In case markets are incomplete such that either the degree of incompleteness is 1 or the sets of efficient production plans are 1-dimensional, a  $\frac{1}{2}$ MSE exists for simple majority voting, i.e. with  $\frac{1}{2} = \frac{1}{2}$ , as argued by DeMarzo (1993). It is shown here that in case of a more severe degree of incompleteness and higher dimensions of the sets of efficient production plans, super majority rules ( $\frac{1}{2} > \frac{1}{2}$ ) are needed to ensure existence of  $\frac{1}{2}$ MSE.

The social choice literature offers some general results on existence of stable equilibria under super majority voting { see, e.g., Ferejohn & Grether (1974), Greenberg (1979), Caplin & Nalebuff (1988, 1991) and Balasko & Cripps (1997). Cripps (2000) exploits the results of Caplin & Nalebuff (1988, 1991) to obtain some conditions on the distribution of consumers' characteristics under which a  $\frac{1}{2}$ MSE exists for  $\frac{1}{2}$  between 0.5 and 0.64 in a model with a continuum of consumers, restrictive assumptions on production sets and preferences of consumers. Here the result of Greenberg (1979) is exploited to obtain a lower bound on the rate  $\frac{1}{2}$  for which a  $\frac{1}{2}$ MSE exists, in a model with a finite number of consumers, weak assumptions on production sets and preferences, and no assumptions on the distribution of consumers' characteristics. A difficulty in applying the results from the social choice

---

<sup>1</sup>See Magill & Quinzii (1996), chapter 6. Actually, existence of  $\frac{1}{2}$ MSE for  $\frac{1}{2} = 0$  holds in any model with incomplete markets where equilibrium allocations are Pareto optimal, e.g., under strong conditions for the CAPM (Borch (1968) and Wilson (1968)).

literature is that preferences of shareholders, as well as shares (i.e. voting weights), are endogeneously determined through general equilibrium effects.

Even though the proposed bounds on  $\frac{1}{2}$  are quite high and cannot be improved, as shown by an example, the results of the present paper show that: (1) the degree of market incompleteness plays a fundamental role in restricting the dimension of the set of alternatives and thereby in aggregating preferences of shareholders and (2) the lower the degree of market incompleteness the lower super majority rate is necessary to ensure existence of a  $\frac{1}{2}$ MSE.

The paper is organized as follows: in Section 2 the model is introduced; in Section 3 assumptions are stated, existence of a  $\frac{1}{2}$ MSE, for  $\frac{1}{2}, \min_f (S_j - J) = (S_j - J + 1); B = (B + 1)g$ , is established in case voting takes place after markets close, and an example is given showing that the latter bound cannot be improved; in Section 4 price perceptions are introduced and existence of a  $\frac{1}{2}$ MSE is established in case voting takes place either before markets open or while they are open, and; finally Section 5 contains some concluding remarks. All proofs are gathered in an appendix.

## 2 The model

Consider an economy with 2 dates,  $t \in \{0, 1\}$ , 1 state at the first date,  $s = 0$ , and  $S$  states at the second date,  $s \in \{1, \dots, S\}$ . There are: 1 commodity at every state,  $I$  consumers,  $i \in \{1, \dots, I\}$ , and  $J$  firms,  $j \in \{1, \dots, J\}$ . Consumers are characterized by their consumption sets,  $X_i \subseteq \mathbb{R}^{S+1}$ , endowments,  $\omega_i \in \mathbb{R}^{S+1}$ , preferences described by correspondences,  $P_i : X_i \rightarrow X_i$ , and initial portfolio of shares in firms,  $\alpha_j \in \mathbb{R}^J$  where  $\sum_{i=1}^I \alpha_{ij} = 1$  for all  $j$ . Firms are characterized by their production sets,  $Y_j \subseteq \mathbb{R}^{S+1}$ .

Consumers choose consumption plans,  $x_i \in X_i$ , and portfolios,  $\mu_i \in \mathbb{R}^J$ . Firms choose production plans,  $y_j \in Y_j$ . For convenience, let  $x = (x_i)_{i=1}^I$ ,  $\mu = (\mu_i)_{i=1}^I$ ,  $y = (y_j)_{j=1}^J$ ,  $q = (q_j)_{j=1}^J \in \mathbb{R}^J$  where  $q_j$  is the price of shares in

firm  $j$ ,  $Y = (y_1, \dots, y_J)$  and

$$Q = \begin{matrix} & 0 & & 1 \\ \begin{matrix} \vdots \\ q_1 \\ 0 \\ \vdots \\ 0 \end{matrix} & \begin{matrix} \dots \\ \dots \\ \dots \end{matrix} & \begin{matrix} q_J \\ 0 \\ \vdots \\ 0 \end{matrix} & \begin{matrix} \vdots \\ \vdots \\ \vdots \\ \vdots \end{matrix} \end{matrix}$$

With some abuse of notation,  $q_j$  denotes the price of shares in firm  $j$  as well as the  $j$ 'th column of  $Q$ . The budget set of consumer  $i$  is

$$B_i(Q; Y) = \{x_i \in X_i \mid x_i \cdot p_i + Qx_i + (Y - Q)\mu_i \text{ for some } \mu_i \in \mathbb{R}^J\}$$

and  $x_i$  is a solution to the problem of consumer  $i$  provided that  $x_i \in B_i(Q; Y)$  and  $P_i(x_i) \setminus B_i(Q; Y) = \emptyset$ . Hence, there are no strategic considerations involved in the choices of portfolios. Let  $U_{ij}(x_i; \mu_j; y_j)$  denote the set of production plans for firm  $j$  that make, at the considered allocation  $(x; \mu; y)$ , consumer  $i$  better off, i.e.

$$U_{ij}(x_i; \mu_j; y_j) = \{y_j^0 \in Y_j \mid x_i + (y_j^0 - y_j)\mu_j \in P_i(x_i)\}$$

Next let  $u_j(x; \mu; y; y_j^0)$  denote the set of consumers who are, at the considered allocation  $(x; \mu; y)$ , better off with production plan  $y_j^0$  for firm  $j$  rather than  $y_j$ , i.e.

$$u_j(x; \mu; y; y_j^0) = \{i \in I \mid (x_i, \mu_i) \in U_{ij}(x_i; \mu_j; y_j)\}$$

Then preferences of firms are described, for a fixed rate  $\frac{1}{2}$  of the super majority rule, by correspondences,  $P_j^{\frac{1}{2}}: \prod_{i \in I} X_i \times \mathbb{R}^I \times \prod_{j \in J} Y_j \rightarrow \prod_{j \in J} Y_j$ , defined by

$$P_j^{\frac{1}{2}}(x; \mu; y) = \begin{cases} \emptyset & \text{for } \sum_i \mu_j^+ = 0 \\ \{y_j^0 \in Y_j \mid \frac{\sum_i u_j(x; \mu; y; y_j^0) \mu_j^+}{\sum_i \mu_j^+} > \frac{1}{2}\} & \text{for } \sum_i \mu_j^+ > 0 \end{cases}$$

And  $y_j$  is a solution to the problem of firm  $j$  provided that  $P_j^{\frac{1}{2}}(x; \mu; y) \setminus Y_j = \emptyset$ . Thus, if the production plan is changed from  $y_j$  to  $y_j^0$  then this change is distributed to shareholders proportionally to their shares.

Definition 1  $(q^a; x^a; \mu^a; y^a)$  is a 1/2 majority stable equilibrium provided that

$\sum_i x_i^a \cdot \omega_i + Q^a \omega + (Y^a - Q^a) \mu^a$  and  $x_i^a$  is a solution to the problem of consumer  $i$  for  $(q^a; y^a)$ , i.e.

$$x_i^a \in B_i(Q^a; Y^a) \text{ and } P_i(x_i^a) \setminus B_i(Q^a; Y^a) = \emptyset;$$

for all  $i \in I$ ,

$y_j^a$  is a solution to the problem of firm  $j$  for  $(x^a; \mu^a)$ , i.e.

$$y_j^a \in Y_j^a \text{ and } P_j^{\omega}(x^a; \mu^a; y_j^a) \setminus Y_j^a = \emptyset;$$

for all  $j \in J$ , and,

markets clear, i.e.

$$\sum_i x_i^a = \sum_i \omega_i^a + \sum_j y_j^a \text{ and } \sum_i \mu_i^a = 1$$

for all  $j \in J$ .

### 3 Assumptions and existence of equilibrium

Assumptions on consumers, firms and the production sector are imposed in order to ensure the existence of a 1/2 majority stable equilibrium.

Consumers are supposed to satisfy the following assumptions

(a.1)  $X_i = \mathbb{R}^{S+1}$ ,

(a.2)  $\omega_i \in \mathbb{R}^{S+1}$ ,

(a.3)  $\text{gr } P_i$  is open,

(a.4)  $\{x_i \in \mathbb{R}_+^{S+1} \mid 0 \in P_i(x_i)\}$ ,

- (a.5) for all  $x_i$ , there exists a unique  $\phi_i \in \mathbb{R}_+^S$  such that  $\phi_i \cdot (x_i^0 - x_i) > 0$  for all  $x_i^0 \in P_i(x_i)$  where  $\phi_i^S = f_i$ ,  $\phi_i \in \mathbb{R}_+^{S+1}$ ,  $\sum_{s=1}^S \phi_i^s = 1$ , and,
- (a.6) if  $A \subseteq \mathbb{R}^{S+1}$  is compact then there exists  $x_i(A) \in \mathbb{R}^{S+1}$  such that if  $x_i \in \mathbb{R}^{S+1} \cap (f_i x_i(A) + \mathbb{R}_+^{S+1})$  then  $A \subseteq P_i(x_i)$ .

Assumptions (a.1) and (a.2) imply that consumption sets are unbounded as considered by Balasko (1988) while assumptions (a.3), (a.4), (a.5) and (a.6) are generalizations of equivalent assumptions considered by Balasko (1988) to non-transitive, non-complete and non-differentiable preferences. Assumptions (a.3) and (a.4) are standard continuity and monotonicity assumptions; assumption (a.5) states existence of a unique shadow price vector  $\phi_i(x_i)$  at each consumption bundle  $x_i$ , and; assumption (a.6) generalizes the standard "boundedness from below" property of indifference sets to the present framework where preferences are not necessarily transitive nor complete.

Let  $Z_j \subseteq \mathbb{R}^{S+1}$  be the set of efficient production plans, i.e.

$$Z_j = \{y_j \in \mathbb{R}^{S+1} \mid (f_j y_j + \mathbb{R}_+^{S+1}) \setminus Y_j = f_j y_j\}$$

then firms are supposed to satisfy the following assumptions

- (a.7) the production set,  $Y_j$ , is convex and closed, and,
- (a.8) there exists a compact and  $B$ -dimensional affine set,  $B_j \subseteq \mathbb{R}^{S+1}$ , such that  $Z_j \subseteq B_j$ .

Assumption (a.7) is standard while assumption (a.8) includes "truncated" production sets such as

$$\{y \in \mathbb{R}^{S+1} \mid y^0 \in [\bar{y}, 0] \text{ and } y^s \leq (y^0)^b \text{ for all } s \in \{1, \dots, S\}\}$$

where  $\bar{y} \leq 0$  and  $b \in [0, 1]$ .

Moreover, the production sector of the economy is supposed to satisfy the following assumption

(a.9) production plans for date 1,  $((y_j^s)_{s=1}^S)_{j=1}^J$ , are linearly independent for all production plans in the convex hull of the closure of the set of efficient production plans,  $y_j \in \text{co cl } Z_j$  for all  $j$ .

Assumption (a.9) excludes that firms are able to replicate production plans of each other.

Theorem 1 There exists a 1/2 majority stable equilibrium for all economies which satisfy assumptions (a.1) to (a.9) if and only if

$$\frac{1}{2} \leq \min \left\{ \frac{S_{j=J}}{S_{j=J} + 1}; \frac{B}{B + 1} \right\}$$

Remark: The argument to establish the "if" of the assertion is based on the proofs of Theorem 2 in Greenberg (1979) and the theorem in Shafer & Sonnenschein (1975). A generalized game is constructed where, among other constructions, firms determine production plans that maximize profits with respect to prices which reflect interests of their shareholders and groups of shareholders (one per firm) determine prices for which firms maximize profits. Hence, the original problem of the firm  $i$  which is to find a production plan for which no alternative production plan can be supported by a 1/2 majority of its shareholders is decomposed into profit maximization with respect to firm specific prices and determination of firm specific prices with respect to some artificial preferences for its shareholders.

The argument to establish the "only if" of the assertion is based on the construction of an economy for which no 1/2 majority stable equilibrium with  $\frac{1}{2} < \min \left\{ \frac{S_{j=J}}{S_{j=J} + 1}; \frac{B}{B + 1} \right\}$  exists.

End of remark

In case  $S_{j=J} = 1$ , Theorem 1 ensures existence of a simple majority stable equilibrium. It is easily seen that the prices for which firms maximize profits are, in this case, typically not the ones Drèze (1974) suggests. Indeed, in theorem 1 the shadow price vector of the median shareholder is used whereas Drèze (1974) suggests that the average shadow price vector should be used.

Trading on the financial markets, when consumers are not constrained in their portfolio choices, leads to suitable normalized shadow prices being contained in some  $(S_j - J)$ -dimensional affine set  $(\sum_{i=1}^I Y^i_j - Q^i_j) \in \mathbb{R}_+^S$ . However, if there are restrictions on portfolios, like short sales constraints, then the degree of market incompleteness need not restrict shadow prices.

Corollary 1 Suppose that portfolios are bounded such that  $\mu_i \in [0; 1]^J$  for all  $i$  and that  $\sum_{i=1}^I Y^i_j \in \mathbb{R}_+^{S+1}$  for all  $j$ . Then there exists a 1/2 majority stable equilibrium provided that

$$\frac{1}{2} \leq \frac{B}{B + 1}$$

It is hard to love the assumption that  $\sum_{i=1}^I Y^i_j \in \mathbb{R}_+^{S+1}$  for all  $j$ . However, the "Cass-trick" { one consumer trades on complete markets } cannot be applied in corollary 1 because portfolios are bounded to be between 0 and 1. Therefore existence of equilibrium is only ensured provided that prices of shares are positive as explained by Radner (1972) and the assumption ensures this.

## 4 Price perceptions

In the present section different timings between trade and vote are considered. At a 1/2 majority stable equilibrium,  $(q^a; x^a; \mu^a; y^a)$ , if consumer  $i$  considers how to vote with regard to a change from  $(q^a; y_j^a)$  to  $(q; y_j)$  of price and production plan for firm  $j$  (where  $\mu_j^a > 0$  or  $\mu_j^a > 0$  because otherwise consumer  $i$  have no voting weight) then

<sup>2</sup> in case voting takes place after markets close, she votes for the change if and only if

$$x_i^a + (Y^a_j y_j - Y^a_j) \mu_i^a \geq P_i(x_i^a)$$

where  $Y^a_j y_j$  is  $Y^a_j$  with  $y_j$  replacing  $y_j^a$ ,

<sup>2</sup> in case voting takes place while markets are open, she votes for the change if and only if

$$x_i^a - (Y_i - Q_j^a) \mu_i^a + (Y_j^a y_j - Q_j^a q) \mu_i^a \geq P_i(x_i^a)$$

for some  $\mu_i$ , and,

<sup>2</sup> in case voting takes place before markets open, she votes for the change if and only if

$$x_i^a - (Q_i - Q_j^a) \mu_i^+ + (Y_j^a y_j - Q_j^a q) \mu_i^+ \geq P_i(x_i^a)$$

for some  $\mu_i$  (here the voting weights are  $\mu_i^+$ ).

If portfolios are unbounded, i.e.  $\mu_i \in \mathbb{R}^J$ , then  $x_i^a \in \mathbb{R}^J$  at a  $\frac{1}{2}$ majority stable equilibrium,  $(q^a; x^a; \mu^a; y^a)$ . Therefore in case voting takes place after markets close (resp. while markets are open or before they open), if consumer  $i$  votes for the change then  $x_i^a - (y_j - y_j^a) > 0$  (resp.  $x_i^a - (q_j - q_j^a) > 0$  or  $x_i^a - (y_j - q_j) \leq 0$ ). Thus, equivalently, in case voting takes place after markets close (resp. while markets are open or before they open), if  $x_i^a - (y_j - y_j^a) \cdot 0$  (resp.  $x_i^a - (q_j - q_j^a) \cdot 0$  and  $x_i^a - (y_j - q_j) = 0$ ) then consumer  $i$  votes against the change. However, consumers do not know how prices depend on production plans so if voting takes place before or while markets are open then they need to form perceptions about this.

## 4.1 Competitive price perceptions

Grossman & Hart (1979) introduced the notion of competitive price perceptions in a model where production plans are determined by shareholders before markets open. Consider a  $\frac{1}{2}$ majority stable equilibrium,  $(q^a; x^a; \mu^a; y^a)$ , then a change of production plan from  $y_j^a$  to  $y_j$  for firm  $j$  is perceived by consumer  $i$  to change the price from  $q_j^a$  to

$$q_j(x_i^a; y_j) = \frac{1}{x_i^a - (y_j - y_j^a)} x_i^a - (y_j - y_j^a)$$

Consequently, if consumer  $i$  votes for the change and has competitive price perception then  $^1_i(x_i^a) \phi(y_j \text{ i } y_j^a) > 0$  and, equivalently, if  $^1_i(x_i^a) \phi(y_j \text{ i } y_j^a) \cdot 0$  then consumer  $i$  votes against the change. This does not depend on whether voting takes place before markets open, while they are open or after they close. Informally, if consumers have competitive price perceptions then they concentrate on how changes of production plans change values of their portfolios rather than the span of assets.

Thus, there is a different interpretation of the model of Section 2 as well as the results of Section 3: voting takes place while markets are open and consumers have competitive price perceptions. Moreover, Theorem 1 and Corollary 1 extend to the model with voting before markets open provided that consumers have competitive price perceptions. However in this latter case the set of equilibria is typically not identical to the set of equilibria of the former case because voting weights typically are not identical, i.e.  $\mu_i^a \notin \pm$ . Hence, the next corollary follows from the proof of Theorem 1 with only minor modifications.

Corollary 2 Suppose that voting takes place before markets open, while they are open or after they close and that consumers have competitive price perceptions. Then there exists a  $\frac{1}{2}$ majority stable equilibrium provided that

$$\frac{1}{2} \leq \min \left\{ \frac{S_i \text{ J } B}{S_i \text{ J } + 1}; \frac{B}{B + 1} \right\}$$

## 4.2 Fixed price perceptions

Consider a  $\frac{1}{2}$ majority stable equilibrium,  $(q^a; x^a; \mu^a; y^a)$ , then a change of production plan from  $y_j^a$  to  $y_j$  for firm  $j$  is perceived by consumer  $i$  not to change the price,  $q^a$ . Informally, if consumers have fixed price perceptions then they concentrate on how changes of production plans change the span of assets rather than values of portfolios.

Portfolios are bounded between 0 and 1, i.e.  $\mu_i \in [0; 1]^J$ , so the modified

budget set of consumer  $i$  is

$$B_i(Q; Y) = \{x_i \in X_i \mid x_i \cdot p_i + Q\mu_i \leq (Y_i - Q)\mu_i \text{ for some } \mu_i \in [0; 1]^J\}$$

Let

$$B_{ij}(q; x_i; y) = \{y_j^0 \in Y_j \mid y_j^0 \cdot p_j + (Y_j - y_j^0)\mu_j \leq P_i(x_i)\}$$

for some  $\mu_j \in [0; 1]^J$

$$u_j(q; x; y; y_j^0) = \{i \in I \mid \exists \mu_j^0 \in [0; 1]^J \text{ s.t. } y_j^0 \in B_{ij}(q; x_i; y)\}$$

then preferences of firms are described by correspondences,  $P_j^{1/2}: R^J \times \prod_{i \in I} X_i \times \prod_{i \in I} [0; 1]^J \times \prod_{j \in J} Y_j \rightarrow \prod_{j \in J} Y_j$ , defined by

$$P_j^{1/2}(q; x; \mu; y) = \begin{cases} \emptyset & \text{for } \sum_{i \in I} \mu_j^+ = 0 \\ \{y_j^0 \in Y_j \mid \exists \mu_j^+ \in [0; 1]^J \text{ s.t. } y_j^0 \in B_{ij}(q; x_i; y) \text{ for } \sum_{i \in I} \mu_j^+ > 0\} & \text{for } \sum_{i \in I} \mu_j^+ > 0 \end{cases}$$

in case voting takes place while markets are open and  $\mu_j$  replaces  $\mu_j^+$  in case voting takes place before markets open.

Corollary 3 Suppose that portfolios are bounded such that  $\mu_j \in [0; 1]^J$  for all  $i$ , that  $\omega_j \in Z_j \subset R_+^{S+1}$  for all  $j$  and that consumers have fixed price perceptions. Then a majority stable equilibrium exists provided that

$$\frac{1}{2} > \frac{B}{B + 1}$$

## 5 Final remarks

In the present paper, bounds on  $\frac{1}{2}$  are provided such that majority stable equilibria exist. To complement these results on existence of equilibrium it would be nice study: (1) the efficiency properties of equilibrium allocations, and; (2) the "size" of the set of equilibria.

On the one hand, in many countries, simple majority voting is used in assemblies of shareholders. On the other hand, the provided bounds on  $\frac{1}{2}$  implies that simple majority stable equilibria need not exist unless either the degree of incompleteness is 1 or the sets of efficient production plans are 1-dimensional. Therefore it would be interesting to find "reasonable" assumptions on production sets and preferences of consumers that ensure existence of  $\frac{1}{2}$  majority stable equilibria for lower values of  $\frac{1}{2}$

## Appendix

### Proof of Theorem 1

In part 1, resp. part 2, it is shown that if  $\frac{1}{2}, (S_i, J) = (S_i, J + 1)$ , resp.  $\frac{1}{2}, B = (B + 1)$ , then a  $\frac{1}{2}$ majority stable equilibrium exists. In part 3, an example is provided of an economy for which no  $\frac{1}{2}$ majority stable equilibrium with  $\frac{1}{2} < \min_i (S_i, J) = (S_i, J + 1); B = (B + 1)$  exists.

Part 1:  $\frac{1}{2}, (S_i, J) = (S_i, J + 1)$

The variables to be determined are state prices,  $\phi \in \mathbb{R}_+^S$ , consumption bundles for consumers,  $x = (x_i)_{i=1}^I \in \mathbb{R}_+^I$ , production plans for firms,  $y = (y_j)_{j=1}^J \in \mathbb{R}_+^J$ , and prices with respect to which firms maximize profits,  $q = (q_j)_{j=1}^J \in \mathbb{R}_+^J$ .

The auctioneer (agent 0) determines state prices in order to maximize the value of excess demand. Consumers (agent  $k \in \{1, \dots, I\}$ ) determine maximal consumption bundles for their preferences. Firms (agent  $k \in \{I + 1, \dots, I + J\}$ ) determine production plans that maximize profits with respect to prices which reflect interests of their shareholders. Groups of shareholders (agent  $k \in \{I + J + 1, \dots, I + 2J\}$ , one group per firm) determine prices for which firms maximize profits. Hence, the original problem of the firm which is to find a production plan for which no alternative production can be supported by a majority of its shareholders is decomposed into profit maximization with respect to firm specific prices and determination of firm specific prices with respect to some artificial preferences for its shareholders.

In a first step, these four categories of agents (auctioneer, consumers, firms and groups of shareholders) are described. In a second step, a suitable correspondence is constructed and Kakutani's fixed point theorem is applied. Finally, in a third step, the fixed point is shown to be a majority stable equilibrium.

Step 1: description of agents

"Auctioneer" For agent  $k = 0$ , the strategy set,  $V_k \in \mathbb{R}_+^{S+1}$ , is defined by

$$V_k = \mathbb{R}_+^S \times \left[\frac{1}{n}, 1\right]^{S+1}$$

where  $n \in \mathbb{N}$ , the constraint correspondence,  $C_k : V \rightarrow V_k$  (where  $V$  is the product of the agents' strategy sets, to be defined in the sequel), is defined by

$$C_k(\phi, x, y, q) = V_k$$

and the preference correspondence,  $Q_k : V \rightarrow V_k$ , is defined by

$$Q_k(s; x; y; \theta) = \{x_i^0 \in V_k \mid \exists x_i^1, \dots, x_i^I, y_j \in X_j \text{ s.t. } \phi(x_i^0, x_i^1, \dots, x_i^I, y_j) > \theta\}$$

Clearly,  $V_k$  is compact and convex,  $C_k$  is continuous and  $\text{gr } Q_k$  is open with  $s_i \in \text{co } Q_k(s; x; y; \theta)$ .

"Consumers" For agent  $k \in \{1, \dots, I\}$ , the strategy set,  $V_k \subseteq X_i$  where  $i = k$ , is defined by

$$V_k = X_i \setminus \left( \bigcup_{j \neq k} Z_j + [0, n]^{S+1} \right)$$

where  $n \in \mathbb{N}$ , the constraint correspondence,  $C_k : V \rightarrow V_k$ , is defined by

$$C_k(s; x; y; \theta) = \{x_i^0 \in V_k \mid \exists x_i^1, \dots, x_i^I, y_j \in Y_j \text{ s.t. } \phi(x_i^0, x_i^1, \dots, x_i^I, y_j) > \theta\}$$

for  $k = 1$  where  $q = (1, \dots, 0)$ ,  $\phi_j$  for all  $j$  and

$$C_k(s; x; y; \theta) = B_i(Y; Q) \setminus V_k$$

for  $k \in \{2, \dots, I\}$  and the preference correspondence,  $Q_k : V \rightarrow V_k$ , is defined by

$$Q_k(s; x; y; \theta) = \text{co } P_i(x_i) \setminus V_k$$

Clearly,  $V_k$  is compact and convex,  $C_k$  is continuous and  $\text{gr } Q_k$  is open with  $x_i \in \text{co } Q_k(s; x; y; \theta)$  for  $i = k$ .

"Firms" For agent  $k \in \{I+1, \dots, I+J\}$ , the strategy set,  $V_k \subseteq Y_j$ , is defined by

$$V_k = \text{co } Z_j$$

where  $j = k - I$ , the constraint correspondence,  $C_k : V \rightarrow V_k$ , defined by

$$C_k(s; x; y; \theta) = V_k$$

and the preference correspondence,  $Q_k : V \rightarrow V_k$ , defined by

$$Q_k(s; x; y; \theta) = \{y_j^0 \in Z_j \mid \exists y_j^1, \dots, y_j^J \text{ s.t. } \phi(y_j^0, y_j^1, \dots, y_j^J) > \theta\} \setminus V_k$$

Clearly,  $V_k$  is compact and convex,  $C_k$  is continuous and  $\text{gr } Q_k$  is open with  $y_j \notin \text{co } Q_k(s; x; y; 0)$  for  $j = k, i \neq k$ .

\ Shareholders" For agent  $k \in \{1, \dots, I+2J\}$ , the strategy set,  $V_k \subseteq \mathbb{R}^{S+1}$ , is defined by

$$V_k = \phi_+^S;$$

the constraint correspondence,  $C_k : V \rightarrow V_k$ , is defined by

$$C_k(s; x; y; 0) = \{y_j^0 \in V_k \mid y_j^0 \in hY_i \cap Q_i^? g\}$$

where  $j = k, i \neq k, i \in J$ . Let the correspondence  $F_i : V_i \times V_k \rightarrow V_k$  where  $i \in \{1, \dots, I\}$  be defined by

$$F_i(x_i; 0_j) = \{y_j^0 \in V_k \mid k^0_j \cdot 1_i(x_i) < k^0_j \cdot 1_i(x_i) kg\}$$

where  $j = k, i \neq k, i \in J$  and let the correspondence  $G_j : \prod_{i=1}^I V_i \times V_k \times V_k \rightarrow \mathbb{R}^J$  be defined by

$$G_j(x; 0_j; 0_j) = \{f_i \in \mathbb{R}^J \mid f_i \in G_j^0 \cap F_i(x_i; 0_j) g\}$$

Then the preference correspondence,  $Q_k : V \rightarrow V_k$ , is defined by

$$Q_k(s; x; y; 0) = \begin{cases} \emptyset & \text{for } \sum_i \hat{y}_{ij}(s; x; y)^+ = 0 \\ \{y_j^0 \in V_k \mid \frac{\sum_i G_i^0(s; x; y; 0) \hat{y}_{ij}(s; x; y)^+}{\sum_i \hat{y}_{ij}(s; x; y)^+} > \frac{1}{g}\} & \text{for } \sum_i \hat{y}_{ij}(s; x; y)^+ > 0 \end{cases}$$

where  $j = k, i \neq k, i \in J$  and  $\hat{y}_i : V_0 \times \prod_{i=1}^I V_i \times \prod_{j=1}^J Z_j \rightarrow \mathbb{R}^J$  is defined by

$$\hat{y}_i(s; x; y) = \text{argmin } \{x_i \mid \sum_i Q_{\pm i}(Y_i \cap Q_i) \hat{y}_i k; \text{ st. } \hat{y}_i \in \mathbb{R}^J\}$$

Clearly,  $V_k$  is compact and convex and  $C_k$  is continuous. Lemma 1 below shows that  $\text{gr } Q_k$  is open and that  $0_j \notin \text{co } (Q_k(s; x; y; 0) \setminus C_k(s; x; y; 0))$  for  $j = k, i \neq k, i \in J$ .

Lemma 1 The preference correspondence for shareholders,  $Q_k : V \rightarrow V_k$  where  $k \in \{1, \dots, I+J\}$ , has the following properties

$gr Q_k$  is open, and,

$\emptyset_j \not\subseteq \infty (Q_k(s; x; y; 0) \setminus C_k(s; x; y; 0))$  for  $k = I + J + j$ .

Proof: " $gr Q_k$  is open" Suppose that  $(x_i(n))_{n \in \mathbb{N}} \subset V_i$  converges to  $x_i \in V_i$  and that  $(p_i(x_i(n)))_{n \in \mathbb{N}} \subset \mathbb{R}_+^S$  converges to  $p_i \in \mathbb{R}_+^S$ . Then there exists  $x_i^0 \in P_i(x_i)$  such that  $p_i \cdot \phi(x_i^0 - x_i) = 0$  so there exists  $x_i^0 \in P_i(x_i)$  such that  $p_i \cdot \phi(x_i^0 - x_i) < 0$ . Therefore there exists  $N \in \mathbb{N}$  such that if  $n \geq N$  then  $p_i(x_i(n)) \cdot \phi(x_i^0 - x_i(n)) < 0$  and  $x_i^0 \in P_i(x_i(n))$  according to (a.3). This is a contradiction thus  $p_i : V_i \rightarrow \mathbb{R}_+^S$  is continuous. Clearly, if  $p_i : V_i \rightarrow \mathbb{R}_+^S$  is continuous for all  $i$  then  $gr Q_k$  is open due to the definition of  $Q_k : V \rightarrow V_k$ .

" $\emptyset_j \not\subseteq \infty (Q_k(s; x; y; 0) \setminus C_k(s; x; y; 0))$  for  $k = I + J + j$ " Let  $[r] \in \mathbb{Z}$  be defined by  $[r] \cdot r < [r] + 1$  for all  $r \in \mathbb{R}$  and let  $L_m = \prod_{i=1}^I [r_{ij}(s; x; y)^+ m] \cdot m \prod_{i=1}^I [r_{ij}(s; x; y)^+]$  artificial consumers be defined by

$$T_i = U_i(0_j; x_i)$$

for all  $i \in \{1, \dots, I\}$  and  $m \in \mathbb{N}$  provided that  $m [r_{ij}(s; x; y)] \geq 1$ . Let  $t_j \in \mathbb{R}_+^S \setminus \{0\}$  be defined by

$$t_j(0_j) = [1, \dots, L_m g_j [r_{ij}(s; x; y)^+] > 0 \text{ and } 0_j \in T_j$$

and let  $R_j \subset \mathbb{R}_+^S$  be defined by

$$R_j = \{x_j^0 \in \mathbb{R}_+^S \mid t_j(0_j) \cdot x_j^0 > \frac{1}{2} \sum_{i=1}^I [r_{ij}(s; x; y)^+ m g_j\}$$

If  $0_j \in Q_k(s; x; y; 0)$  then there exists  $\epsilon > 0$  such that

$$\epsilon = \frac{\prod_{i=1}^I [r_{ij}(s; x; y)^+]}{\prod_{i=1}^I [r_{ij}(s; x; y)^+]} \geq \frac{1}{2}$$

due to the definition of  $Q_k : V \rightarrow V_k$ . Therefore,  $0_j \in R_j$  provided that  $m > \frac{1}{\epsilon} \prod_{i=1}^I [r_{ij}(s; x; y)^+]$  so  $Q_k(s; x; y; 0) \not\subseteq \infty [R_j]$ .

Clearly,  $0_j \neq \emptyset (F_i(0_j; x_i) \setminus C_k(, ; x; y; 0))$  due to the construction of  $F_i : \emptyset_+^S \times V_i \rightarrow \emptyset_+^S$  therefore  $0_j \neq \emptyset (R_j \setminus C_k(, ; x; y; 0))$  for all  $m$  because  $\dim C_k(, ; x; y; 0) = S - J$  and  $\frac{1}{2} (S - J) = (S - J + 1)$  hence  $0_j \neq \emptyset (Q_k(, ; x; y; 0) \setminus C_k(, ; x; y; 0))$  according to Greenberg (1979).

Q.E.D.

Step 2: construction of correspondence and existence of fixed point

Let  $K = \{0, \dots, I + 2J\}$  then  $V_k$  is compact and convex for all  $k \in K$  and  $V = \bigcap_{k \in K} V_k$ . Let the map  $f_k : V \times V_k \rightarrow \mathbb{R}_+$  be defined by

$$f_k(z; z_k^0) = \min_{(v; v_k^0) \in \text{gr } Q_k(z)} k(z; z_k^0) - (v; v_k^0)k;$$

the correspondence  $g_k : V \rightarrow V_k$  by

$$g_k(z) = \arg \max_{z_k^0 \in C_k(z)} f_k(z; z_k^0);$$

Then the correspondence,  $h : V \rightarrow V$  defined by  $h(z) = \bigcap g_k(z)$  is upper hemi-continuous and compact and convex valued. Therefore there exists  $(,^m; x_1^m; \dots; x_I^m; y_1^m; \dots; y_J^m; 0^m) = z^m \in Z$  such that  $z^m \in h(z^m)$  according to the Kakutani fixed point theorem. Hence,  $z_k^m \in C_k(z^m)$  and  $Q_k(z^m) \setminus C_k(z^m) = \emptyset$ ; because  $z_k \neq \emptyset Q_k(z) \setminus C_k(z)$ .

Step 3: existence of 1/2 majority stable equilibrium

For consumers, there exists  $x_i(f!_i g + \sum_{j \neq i}^P \alpha_j \text{co } d Z_j) \in \mathbb{R}^{S+1}$  such that if  $x_i \in B_i(Q; Y)$  and  $P_i(x_i) \setminus B_i(Q; Y) = \emptyset$ ; then  $x_i, x_i(f!_i g + \sum_{j \neq i}^P \alpha_j \text{co } d Z_j)$  according to (a.6) because  $f!_i g + \sum_{j \neq i}^P \alpha_j \text{co } d Z_j$  is compact according to (a.7). Therefore there exist  $z^m \in h(z^m)$  and  $N_C \in \mathbb{N}$  such that if  $n \geq N_C$  - recall that  $V_k = X_i \setminus (f!_i g + \sum_{j \neq i}^P \alpha_j \text{co } d Z_j + [i, n; n]^{S+1})$  for  $k = i$  - then  $x_i^m \in B_i(Q^m; Y^m)$  and  $\text{co } P_i(x_i^m) \setminus B_i(Q^m; Y^m) = \emptyset$ ; thus  $x_i^m = !_i + Q^m \alpha_i + (Y^m - Q^m) \mu_i^m$  for some  $\mu_i^m \in [0, 1]^J$ .

For consumers, if  $x_1(n) \leq x_1^0$ , where  $x_1^s(n) \leq x_1^0$  and  $x_1^s = 0$  for  $s \geq 1$ .  $S$  and  $x_1(n) \in C_1(x(n); y(n); 0(n))$  and  $Q_1(x(n); y(n); 0(n)) \setminus C_1(x(n); y(n); 0(n)) = \emptyset$ ; then  $\sum_{s \geq 1} x_1^s(n) \leq x_1^0$  according to (a.3) and (a.4) while consumption is bounded from below for all consumers according to (a.6). Therefore, for the auctioneer, there exists  $N_A \geq N$  such that if  $n \geq N_A$  - recall that  $V_k = \emptyset \setminus [1; n]^{S+1}$  for  $k = 0$  - and  $z^n \in h(z^n)$  then  $\sum_i x_i^n = \sum_i x_i^0 + \sum_j y_j^n$ .

For the firms, if  $z^n \in h(z^n)$  then  $y_j^n \in \arg \max_{y_j} u_j(y_j; z_j^n)$ ; s.t.  $y_j \in \text{co} d_j Z_j$  therefore  $y_j^n \in \arg \max_{y_j} u_j(y_j; z_j^n)$ ; s.t.  $y_j \in Y_j$  and  $Y_j \cap \{y_j \mid f_j(y_j)g + h_j^n \leq 0\} \neq \emptyset$ .

Lemma 2 If  $z^n \in h(z^n)$  and  $n \geq N_C$  then  $P_j^{1/2}(x^n; \mu_j^n; y_j^n) = \emptyset$ .

Proof: Suppose that  $n \geq N_C$ , if  $x_i^n + (y_j - y_j^n) \mu_j^n \in P_i(x_i^n)$  and  $\mu_j^n > 0$  then  $1_i(x_i^n) \cap (y_j - y_j^n) > 0$  and if  $1_i(x_i^n) \cap (y_j - y_j^n) \neq \emptyset$  and  $\mu_j^n > 0$  then  $x_i^n + (y_j - y_j^n) \notin P_i(x_i^n)$ . Hence, if

$$\frac{\sum_i H_i(v_j) \mu_j^{n+1}}{\sum_i \mu_j^{n+1}} \leq \frac{1}{2}$$

for all  $v_j \in h_j^n$  where

$$H_j(v_j) = \{i \mid f_i(x_i^n) \cap (y_j - y_j^n) > 0\}$$

then  $P_j^{1/2}(x^n; \mu_j^n; y_j^n) = \emptyset$ ; because  $Y_j \cap \{y_j \mid f_j(y_j)g + h_j^n \leq 0\} \neq \emptyset$ . Thus,  $h_j^n$  separates  $H_j(v_j)$  from the rest of the  $i$ 's in the sense that  $H_j(v_j)$  is above  $h_j^n$  while the rest of the  $i$ 's are below or on  $h_j^n$ , i.e.  $i \in H_j(v_j)$  if and only if  $1_i(x_i^n) \cap (y_j - y_j^n) > 0$ .

For  $v_j \in h_j^n$  suppose that  $\sum_s v_j^s < 1$  without loss of generality and let  $(p(n))_{n \geq N} \in \emptyset$  where  $\emptyset = f_j \in R^{S+1} \prod_{s=1}^S v_j^s = 1g$  be defined by

$$p(n) = \frac{1}{n + \sum_s v_j^s} (n \mu_j^n + v_j):$$

for all  $n$  then  $(p(n))_{n \geq N}$  converges to  $\mu_j^n$ . Let  $(q(n))_{n \geq N} \in h_j^n$  be defined by

$$q(n) = (p(n) - \mu_j^n) \frac{(p(n) - \mu_j^n) \cap (p(n) + \mu_j^n)}{(p(n) + \mu_j^n) \cap (p(n) + \mu_j^n)} (p(n) + \mu_j^n):$$

for all  $n$ . Then some tedious calculations show that  $(nq(n))_{n \geq N}$  converges to  $v_j$  and  $h_j(n)$  separates  $G_j(p; x^n; p(n))$  from the rest of the  $i$ 's in the sense that  $G_j(p; x^n; p(n))$  is above  $h_j(n)$  while the rest of the  $i$ 's are below or on  $h_j(n)$ . Moreover there exists  $N \geq N$  such that if  $n \geq N$  then  $h_j$  separates  $G_j(p; x^n; p(n))$  from the rest of the  $i$ 's in the sense that  $G_j(p; x^n; p(n))$  is above  $h_j$  while the rest of the  $i$ 's are below or on  $h_j$ . Thus if  $n \geq N$  then  $G_j(p; x^n; p(n)) = H_j(v_j)$ . Therefore,  $P_j^{1/2}(x^n; \mu_j^n; y_j^n) = \cdot$ ; because  $Q_{I+J+j}(z^n) = \cdot$ .

Q.E.D.

For shareholders, if  $z^n \geq h_{I+J+j}(z^n)$  then  $P_j^{1/2}(x^n; \mu_j^n; y_j^n) = \cdot$ ; provided that  $n \geq N_C$  according to lemma 2. Thus, if  $1/2 \geq (S_j - J)/(S_j - J + 1)$  and  $n \geq \max\{N_A, N_C\}$  then a  $1/2$  majority stable equilibrium exists.

Part 2:  $1/2, B \geq (B + 1)$

The variables to be determined are state prices,  $p \in \mathbb{R}_+^S$ , consumption bundles for consumers,  $x = (x_i)_{i=1}^I \geq 0$ , and production plans for firms,  $y = (y_j)_{j=1}^J \geq 0$ .

Let strategy sets, constraint correspondences and preference correspondences be defined as in part 1 of the proof for  $k \in \{0, 1, \dots, I\}$ .

"Firms" For agent  $k \in \{I + 1, \dots, I + J\}$ , the strategy set,  $V_k \subseteq \mathbb{R}^{S+1}$ , is defined by

$$V_k = \text{co} \{Z_j\}$$

where  $j = k - I$ , the constraint correspondence,  $C_k : V \rightarrow V_k$ , is defined by

$$C_k(p; x; y) = V_k$$

and the preference correspondence,  $Q_k : V \rightarrow V_k$ , is defined by

$$Q_k(p; x; y) = P_j^{1/2}(x; p_j(p; x; y); y_j) \cap V_k$$

Clearly,  $V_k$  is compact and convex,  $C_k$  is continuous and  $\text{gr } Q_k$  is open with  $y_j \in \infty Q_k(x; y)$  for  $j = k, j \neq k$  according to the proof of theorem 2 in Greenberg (1979).

The rest of the proof follows from part 1. Thus, if  $\frac{1}{2}, B=(B+1)$  then a  $\frac{1}{2}$ majority stable equilibrium exists.

Part 3: an example showing that the bound is binding

Consider an economy with  $S$  consumers with utility functions linear in period zero consumption and log-linear in period 1 consumption. Consumer  $i$  is indexed by weights,  $\frac{1}{4} = (\frac{1}{4})_{s=1}^S$  with  $\prod_{s=1}^S \frac{1}{4} = 1$ , on consumption in different states. The utility function of consumer  $i$  is:

$$u_i(x_i) = x_i^0 + \sum_{s=1}^S \frac{1}{4} \log x_i^s \quad \text{with} \quad \begin{cases} < \frac{1}{4} = \epsilon & \text{if } s \notin i \\ : \frac{1}{4} = 1_i (S_i - 1) \epsilon \end{cases} \quad (1)$$

where  $\epsilon \in ]0; 1[$  is small. Although these utility functions do not satisfy assumption (a.6), since the argument is local they can be easily extended outside the relevant domain to fulfill this assumption. All consumers are endowed with identical initial shares of the  $J$  firms:  $\alpha_j = 1/S$ , for all  $i, j$ , and the same vector of initial resources:  $\omega_i = (\omega; 0; \dots; 0)$ , all  $i$ .

All  $J$  firms have their sets of efficient production plans included in the same  $(S-1)$ -dimensional linear subspace:

$$Y = \{ y = (y^0; y^1; y^2; \dots; y^S) \in \mathbb{R}^S \mid \sum_{s=0}^S y^s = 0 \text{ and } y^0 = -1 \}$$

Define the production plans  $y = (y_j)_{j=1}^J$  by:

$$y_j^s = \begin{cases} \epsilon & \text{for } s = 0 \\ 1 & \text{for } s = j \\ 0 & \text{otherwise} \end{cases}$$

for  $j = J - 1$  and for  $i = 1, \dots, J$

$$y_j^s = \begin{cases} 1 & \text{for } s = 0 \\ \frac{1}{S_j + 1} & \text{for } s = 1, \dots, S_j \\ 0 & \text{otherwise} \end{cases}$$

Next, define  $y = (y_j)_{j=1}^J$  such that  $y_j = y_j$  and  $y_j = \theta y_j + (1 - \theta) y_J$  for  $j = J - 1, \dots, 1$ , with  $\theta = \frac{1}{S_j + 1}$ . Let, for all  $j$ ,  $Z_j = Y \setminus B(y_j; \epsilon)$  where  $B(y_j; \epsilon)$  stands for the ball with center  $y_j$  and radius  $\epsilon$ . This way, an  $(\theta; \epsilon)$ -economy is defined.

Observation 1 For all  $\epsilon$ , there exists  $(\theta; \epsilon)$  such that the  $(\theta; \epsilon)$ -economy does not have a  $\frac{1}{2}$ majority stable equilibrium for  $\frac{1}{2} < (S_j + 1) \leq \frac{1}{\epsilon}$ .

Consider the  $(\theta; \epsilon)$ -economy. It is now shown that there is a unique  $\frac{1}{2}$  majority stable equilibrium (for all  $\epsilon$  since  $\epsilon = 0$  implies there is no alternative production plan),  $(q^a; \mu^a; y^a)$ , with  $y^a = y$  and  $q^a = \frac{1}{S_j + 1} e_j$  where  $e_j = (0, \dots, 1, \dots, 0)$ .

For the announced production plans  $y^a$ , the expression of the utility level of agent  $i$  buying, at price  $q^a$ , the portfolio  $(\mu_j)_{j=1}^J$  is:

$$U_i = \frac{1}{S_j + 1} \sum_{j=1}^J (\frac{1}{S_j + 1})^{\alpha_j} \mu_j + \sum_{s=1}^{S_j} \frac{1}{S_j + 1} \log \left[ \frac{\mu_s}{\sum_{s=1}^{S_j} \mu_s} \right] + \frac{1}{S_j + 1} \log \left[ \frac{\mu_J + (1 - \theta) \mu_U}{\sum_{s=1}^{S_j} \mu_s} \right];$$

where  $U = (U_1, \dots, U_{J-1})$ ,  $V = (V_1, \dots, V_{S_j})$ ,  $\frac{1}{S_j + 1} = \sum_{s=1}^{S_j} \frac{1}{S_j + 1}$  and  $\mu_U = \sum_{j=2}^J \mu_j$ .

First-order conditions of this maximization problem (optimal portfolio choice) gives:

$$\frac{1}{S_j + 1} \sum_{j=1}^J \frac{1}{S_j + 1} + \frac{(1 - \theta) \frac{1}{S_j + 1}}{\mu_J + (1 - \theta) \mu_U} = \frac{1}{S_j + 1} + 1; \text{ and } \frac{1}{S_j + 1} = \frac{1}{S_j + 1} + 1;$$

which in turn yields:

$$\frac{1}{S_j + 1} \sum_{j=1}^J \frac{1}{S_j + 1} = \frac{1}{S_j + 1} + 1; \text{ and } \mu_J = \frac{1}{S_j + 1} \left[ \frac{1 - \theta}{\theta} \frac{1}{S_j + 1} \right];$$

It is easily checked that stock markets clear, as well as markets for good, for the chosen values of  $\theta = J/S$  and under the equilibrium price  $\bar{p} = S/J$ . Then the equilibrium portfolio is:

$$s_i = \frac{1}{J+1} \left( \frac{1}{S} \right)^{1/J}; \text{ and } \mu_{iJ}^p = \frac{1}{S} \left( \frac{1}{J+1} \right)^{1/J};$$

which is such that  $\sum_{j=1}^J \mu_{ij}^p = \frac{1}{S}$  for all  $i$ .

Suppose now that firm  $J$  is given the opportunity to propose a small change of its production plan. For  $\epsilon$  small enough, one has  $\mu_{iJ}^p > 0$  for  $J \cdot i \cdot S$  and  $\mu_{iJ}^p < 0$  for  $0 \cdot i \cdot J \cdot 1$ . Hence, only the  $S \cdot J + 1$  last consumers have a positive quantity of shares in firm  $J$  and consequently they are the only ones to vote, with the same voting weights. The utility function of consumer  $i$ ,  $J \cdot i \cdot S$ , has been constructed such that, at this symmetric equilibrium, consumer  $i$  supports a (technically possible) change from  $y_J$  to  $y_J^0$  in  $Z_J$  if and only if  $y_J^i \cdot y_J^0$ , i.e. any change that yields more in state  $i$ . For example,  $y_J^0 = y_J + (0; \dots; 0; \epsilon; \dots; \epsilon) = (S \cdot J) \cdot (0; \dots; 0; \epsilon; \dots; \epsilon)$  gets the support of the last  $S \cdot J$  shareholders/shares. Hence,  $(q^p; \mu^p; y^p)$  is not stable for any super majority rule of size smaller than  $(S \cdot J) \cdot (S \cdot J + 1)$ . Subject to the obvious upper hemi-continuity of the equilibrium correspondence in the present setup, any  $\frac{1}{2}$ majority stable equilibrium of the  $(\epsilon; 0)$ -economy, for  $\epsilon$  and  $0$  small enough, is such that  $\frac{1}{2} > (S \cdot J) \cdot (S \cdot J + 1) \cdot \epsilon$ . Finally, note that  $S \cdot J \cdot B = S \cdot 1$  so there is no need to consider the other case which is more obvious.

## Proof of Corollary 1

The variables to be determined are prices,  $p \in \mathbb{R}_+^J$ , consumption bundles for consumers,  $x = (x_i)_{i=1}^I \in \mathbb{R}_+^I$ , and production plans for firms,  $y = (y_j)_{j=1}^J \in \mathbb{R}_+^J$ .

"Auctioneer" For agent  $k = 0$ , the strategy set,  $V_k \in \mathbb{R}^{J+1}$ , is defined by

$$V_k = \mathbb{R}_+^J \setminus \left[ \frac{1}{n}; 1 \right]^{J+1}$$

where  $n \in \mathbb{N}$ , the constraint correspondence,  $C_k : V \rightarrow V_k$ , is defined by

$$C_k(p; x; y) = V_k$$

and the preference correspondence,  $Q_k : V \rightarrow V_k$ , is defined by

$$Q_k(p; x; y) = \{ p^0 \in V_k \mid (p^0_i, p_0) \left( \sum_i x_i^0, \sum_i z_i^0, \sum_j y_j^0 \right) + \sum_j (p_j^0 - p_j) \left( \sum_i z_{ij}(p; x; y) - 1 \right) > 0 \}$$

where  $q_j = p_j = p_0$  for all  $j$  and  $z_i : V_0 \times \prod_{i=1}^Q V_i \times \prod_{j=1}^J Z_j \rightarrow [0, 1]^J$  is defined by

$$z_i(p; x; y) = \operatorname{argmin} \{ \sum_j z_{ij} \mid \sum_j z_{ij} (Y_j - Q_j) z_{ij} \leq k; \text{ s.t. } z_{ij} \in [0, 1]^J \}$$

for all  $i$ . Clearly,  $V_k$  is compact and convex,  $C_k$  is continuous and  $gr Q_k$  is open with  $p \in co Q_k(p; x; y)$ .

\ Consumers" As in part 1 in the proof of theorem 1 - restricting portfolios to  $[0, 1]^J$  and disregarding  $\phi$ .

\ Firms" As in part 2 in the proof of theorem 1 - restricting portfolios to  $[0, 1]^J$  in the definition of  $P_j^{1/2}(x; \mu; y_j)$ , replacing  $\mu_j$  with  $z_j(p; x; y)$  and disregarding  $\phi$ .

The rest of the proof follows from the last part of part 1 in the proof theorem 1.

### Proof of Corollary 3

Proof: Follows from the proof of Theorem 1 with minor changes provided that  $x_i \in B_i(Q; Y)$  and  $P_i(x_i) \cap B_i(Q; Y)$  imply that  $y_j \in co B_{ij}(q; x_i; y_j)$ .

Hence, suppose that  $(y_j(n))_{n=1}^N \in B_{ij}(q; x_i; y)$  where  $N \in \mathbb{N}$  then there exists  $(\mu(n))_{n=1}^N$  such that  $x_i + (Y_j y_j(n) - Q_j) \mu(n) \in P_i(x_i)$  for all  $n \in \{1, \dots, N\}$ . Suppose that  $y_j^0 = \sum_n \alpha(n) y_j(n)$  where  $\alpha(n) \geq 0$  for all  $n$  and

$\prod_{n=1}^N \mathbb{Q}(n) = 1$  and let  $\mu_j^0$  and  $(\bar{\pi}(n))_{n=1}^N$  where  $\bar{\pi}(n) \geq 0$  for all  $n$  and  $\prod_{n=1}^N \bar{\pi}(n) = 1$  be defined by  $\mathbb{Q}(n)\mu_j^0 = \bar{\pi}(n)\mu_j(n)$  for all  $n$  and  $\mu_{j_0}^0 = \prod_{n=1}^N \bar{\pi}(n)\mu_{j_0}(n)$  for all  $j_0 \in J$ . Then

$$x_i + (Y_j y_j^0 - i - Q)\mu_i^0 = \sum_{n=1}^N \bar{\pi}(n)(x_i + (Y_j y_j(n) - i - Q)\mu_i(n)).$$

Therefore, if  $x_i \in \mathcal{B}_i(Q; Y)$  and  $P_i(x_i) \setminus \mathcal{B}_i(Q; Y)$  then  $y_j \notin \mathcal{B}_{ij}(q; x_i; y_j)$ .

It is necessary to bound portfolios to be non-negative in order to ensure that there exists  $\mu^0$  and  $(\bar{\pi}(n))_n$  such that  $(Y_j y_j^0 - i - Q)\mu_i^0 = \prod_{n=1}^N \bar{\pi}(n)(Y_j y_j(n) - i - Q)\mu_i(n)$ .
